Functional Description

The 16-Bit shift register operates in one of four modes, as determined by the signals applied to the Chip Select (\overline{CS}), Read/Write (R/W) and Store Clock Pulse (STCP) input. State changes are indicated by the falling edge of the Shift Clock Pulse (SHCP). In the Shift Right mode, data enters D_0 from the Serial Input (SI) pin and exits from Q_{15} via the Serial Data Output (SO) pin. In the Parallel Load mode, data from the storage register outputs enter the shift register and serial shifting is inhibited.

The storage register is in the Hold mode when either $\overline{\text{CS}}$ or R/W is HIGH. With CS and R/W both LOW, the storage register is parallel loaded from the shift register on the rising edge of STCP.

To prevent false clocking of the shift register, SHCP should be in the LOW state during a LOW-to-HIGH transition of CS. To prevent false clocking of the storage register, STCP should be LOW during a HIGH-to-LOW transition of CS if R/\overline{W} is LOW, and should also be LOW during a HIGH-to-LOW transition of R/\overline{W} if \overline{CS} is LOW.

Note 1: Absolute maximum ratings are values beyond which the device may be damaged or have its useful life impaired. Functional operation under these conditions is not implied.

Note 2: Either voltage limit or current limit is sufficient to protect inputs.
