

### FEATURES

#### Low Noise

2.1 nV/ $\sqrt{\text{Hz}}$  Input Voltage Noise

2.1 pA/ $\sqrt{\text{Hz}}$  Input Current Noise

#### Custom Compensation

Constant Bandwidth from  $G = -1$  to  $G = -10$

#### High Speed

200 MHz ( $G = -1$ )

190 MHz ( $G = -10$ )

#### Low Power

34 mW or 6.7 mA Typ for 5 V Supply

#### Output Disable Feature, 1.3 mA

#### Low Distortion

-93 dB Second Harmonic,  $f_c = 1$  MHz

-108 dB Third Harmonic,  $f_c = 1$  MHz

#### DC Precision

1 mV Max Input Offset Voltage

0.5  $\mu\text{V}/^\circ\text{C}$  Input Offset Voltage Drift

#### Wide Supply Range, 5 V to 24 V

#### Low Price

#### Small Packaging

Available in SOIC-8 and MSOP-8

### APPLICATIONS

ADC Preamp and Driver

Instrumentation Preamp

Active Filters

Portable Instrumentation

Line Receivers

Precision Instruments

Ultrasound Signal Processing

High Gain Circuits

### PRODUCT DESCRIPTION

The AD8021 is a very high performance, high speed voltage feedback amplifier that can be used in 16-bit resolution systems. It is designed to have low voltage and current noise (2.1 nV/ $\sqrt{\text{Hz}}$  typ and 2.1 pA/ $\sqrt{\text{Hz}}$  typ) while operating at the lowest quiescent supply current (7 mA @  $\pm 5$  V) among today's high speed, low noise op amps. The AD8021 operates over a wide range of supply voltages from  $\pm 2.5$  V to  $\pm 12$  V, as well as from single 5 V supplies, making it ideal for high speed, low power instruments. An output disable pin allows further reduction of the quiescent supply current to 1.3 mA.

### CONNECTION DIAGRAM

SOIC-8 (R-8)

MSOP-8 (RM-8)

The AD8021 allows the user to choose the gain bandwidth product that best suits the application. With a single capacitor, the user can compensate the AD8021 for the desired gain with little trade-off in bandwidth. The AD8021 is a very well behaved amplifier that settles to 0.01% in 23 ns for a 1 V step. It has a fast overload recovery of 50 ns.

The AD8021 is stable over temperature with low input offset voltage drift and input bias current drift, 0.5  $\mu\text{V}/^\circ\text{C}$  and 10 nA/ $^\circ\text{C}$ , respectively. The AD8021 is also capable of driving a 75  $\Omega$  line with  $\pm 3$  V video signals.

The AD8021 is not only technically superior, but also priced considerably less than comparable amps drawing much higher quiescent current. The AD8021 is a high speed, general-purpose amplifier, ideal for a wide variety of gain configurations, and can be used throughout a signal processing chain and in control loops.

The AD8021 is available in both standard 8-lead SOIC and MSOP packages in the industrial temperature range of  $-40^\circ\text{C}$  to  $+85^\circ\text{C}$ .

## ABSOLUTE MAXIMUM RATINGS<sup>1</sup>

Supply Voltage	26.4 V
Power Dissipation	Observed Power Derating Curves
Input Voltage (Common-Mode)	$\pm V_S \pm 1$ V
Differential Input Voltage <sup>2</sup>	$\pm 0.8$ V
Differential Input Current	$\pm 10$ mA
Output Short-Circuit Duration	Observed Power Derating Curves
Storage Temperature	$-65^{\circ}\text{C}$ to $+125^{\circ}\text{C}$
Operating Temperature Range	$-40^{\circ}\text{C}$ to $+85^{\circ}\text{C}$
Lead Temperature Range (Soldering, 10 sec)	$300^{\circ}\text{C}$

### NOTES

<sup>1</sup> Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

<sup>2</sup> The AD8021 inputs are protected by diodes. Current-limiting resistors are not used in order to preserve the low noise. If a differential input exceeds  $\pm 0.8$  V, the input current should be limited to  $\pm 10$  mA.

## MAXIMUM POWER DISSIPATION

The maximum power that can be safely dissipated by the AD8021 is limited by the associated rise in junction temperature. The maximum safe junction temperature for plastic encapsulated devices is determined by the glass transition temperature of the plastic, approximately  $150^{\circ}\text{C}$ . Temporarily exceeding this limit may cause a shift in parametric performance due to a change in the stresses exerted on the die by the package. Exceeding a junction temperature of  $175^{\circ}\text{C}$  for an extended period can result in device failure.

While the AD8021 is internally short-circuit protected, this may not be sufficient to guarantee that the maximum junction temperature ( $150^{\circ}\text{C}$ ) is not exceeded under all conditions. To ensure proper operation, it is necessary to observe the maximum power derating curves.

### PIN CONFIGURATION

Figure 2. Maximum Power Dissipation vs. Temperature\*

\*Specification is for device in free air:

8-Lead SOIC:  $\theta_{JA} = 125^{\circ}\text{C}/\text{W}$

8-Lead MSOP:  $\theta_{JA} = 145^{\circ}\text{C}/\text{W}$

### PIN FUNCTION DESCRIPTIONS

Pin No.	Mnemonic	Function
1	LOGIC REFERENCE	Reference for Pin 8* Voltage Level. Connect to logic low supply.
2	-IN	Inverting Input
3	+IN	Noninverting Input
4	-VS	Negative Supply Voltage
5	CCOMP	Compensation Capacitor. Tie to -VS. (See the Applications section for value.)
6	VOUT	Output
7	+VS	Positive Supply Voltage
8	DISABLE	Disable, Active Low*

\*When Pin 8 (DISABLE) is about 2 V or more higher than Pin 1 (LOGIC REFERENCE), the part is enabled. When Pin 8 is brought down to within about 1.5 V of Pin 1, the part is disabled. (See the Specification tables for exact disable and enable voltage levels.) If the disable feature is not going to be used, Pin 8 can be tied to +VS or a logic high source, and Pin 1 can be tied to ground or logic low. Alternatively, if Pin 1 and Pin 8 are not connected, the part will be in an enabled state.

### ORDERING GUIDE

\*Z = Lead Free

### CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD8021 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## APPLICATIONS

The typical voltage feedback op amp is frequency stabilized with a fixed internal capacitor,  $C_{INTERNAL}$ , using dominant pole compensation. To a first-order approximation, voltage feedback op amps have a fixed gain bandwidth product. For example, if its  $-3$  dB bandwidth for  $G = +1$  is 200 MHz, at a gain of  $G = +10$  its bandwidth will be only about 20 MHz. The AD8021 is a voltage feedback op amp with a minimal  $C_{INTERNAL}$  of about 1.5 pF. By adding an external compensation capacitor,  $C_C$ , the user can circumvent the fixed gain bandwidth limitation of other voltage feedback op amps.

Unlike the typical op amp with fixed compensation, the AD8021 allows the user to

1. Maximize the amplifier bandwidth for closed-loop gains between 1 and 10, avoiding the usual loss of bandwidth and slew rate.
2. Optimize the trade-off between bandwidth and phase margin for a particular application.
3. Match bandwidth in gain blocks with different noise gains, such as when designing differential amplifiers (as shown in Figure 10).

Figure 3. Simplified Diagram of Open-Loop Gain and Phase Response

Figure 3 is the AD8021 gain and phase plot that has been simplified for instructional purposes. If the desired closed-loop gain is  $G = +1$  and  $C_C = 10$  pF is chosen, Arrow A of the figure shows that the bandwidth is about 200 MHz and the phase margin is about  $60^\circ$ . If the gain is changed to  $G = +10$  and  $C_C$  is fixed at 10 pF, then (as expected for a typical op amp) the

bandwidth is degraded to about 20 MHz and the phase margin increases to  $90^\circ$  (Arrow B). However, by reducing  $C_C$  to zero, the bandwidth and phase margin return to about 200 MHz and  $60^\circ$  (Arrow C), respectively. In addition, the slew rate is dramatically increased, as it roughly varies with the inverse of  $C_C$ .

Figure 4. Suggested Compensation Capacitance vs. Gain for Maintaining 1 dB Peaking

Table I and Figure 4 provide recommended values of compensation capacitance at various gains and the corresponding slew rate, bandwidth, and noise. Note that the value of the compensation capacitor depends on the circuit noise gain, not the voltage gain. As shown in Figure 5, the noise gain,  $G_N$ , of an op amp gain block is equal to its noninverting voltage gain, regardless of whether it is actually used for inverting or noninverting gain. Thus,

$$\text{Noninverting } G_N = R_F / R_G + 1$$

$$\text{Inverting } G_N = R_F / R_G + 1$$

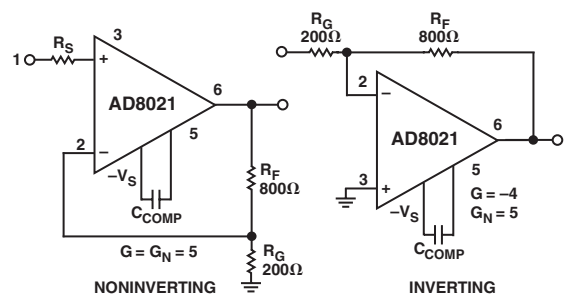

Figure 5. The Noise Gain of Both Is 5

# AD8021

With the AD8021, a variety of trade-offs can be made to fine-tune its dynamic performance. Sometimes more bandwidth or slew rate is needed at a particular gain. Reducing the compensation capacitance, as illustrated in TPC 3, will increase the bandwidth and peaking due to a decrease in phase margin. On the other hand, if more stability is needed, increasing the compensation cap will decrease the bandwidth while increasing the phase margin.

As with all high speed amplifiers, parasitic capacitance and inductance around the amplifier can affect its dynamic response. Often, the input capacitance (due to the op amp itself, as well as the PC board) could have a significant effect. The feedback resistance, together with the input capacitance, may contribute to a loss of phase margin, thereby affecting the high frequency response, as shown in TPC 10. Furthermore, a capacitor ( $C_F$ ) in parallel with the feedback resistor can compensate for this phase loss.

Additionally, any resistance in series with the source will create a pole with the input capacitance (as well as dampen high frequency resonance due to package and board inductance and capacitance), the effect of which is shown in TPC 11.

It must also be noted that increasing resistor values will increase the overall noise of the amplifier, and that reducing the feedback resistor value will increase the load on the output stage, thus increasing distortion (TPC 18).

### Using the Disable Feature

When Pin 8 (DISABLE) is approximately 2 V or more higher than Pin 1 (LOGIC REFERENCE), the part is enabled. When Pin 8 is brought down to within about 1.5 V of Pin 1, the part is disabled. See the Specification tables for exact disable and enable voltage levels. If the disable feature is not going to be used, Pin 8 can be tied to  $V_S$  or a logic high source, and Pin 1 can be tied to ground or logic low. Alternatively, if Pin 1 and Pin 8 are not connected, the part will be in an enabled state.

### THEORY OF OPERATION

The AD8021 is fabricated on the second generation of Analog Devices' proprietary High Voltage eXtra-Fast Complementary Bipolar (XFCB) process, which enables the construction of PNP and NPN transistors with similar  $f_T$ s in the 3 GHz region. The transistors are dielectrically isolated from the substrate (and each other), eliminating the parasitic and latch-up problems caused by junction isolation. It also reduces nonlinear capacitance (a source of distortion) and allows a higher transistor  $f_T$  for a given quiescent current. The supply current is trimmed, which results in less part-to-part variation of bandwidth, slew rate, distortion, and settling time.

As shown in Figure 6, the AD8021 input stage consists of an NPN differential pair in which each transistor operates at 0.8 mA collector current. This allows the input devices a high transconductance; thus, the AD8021 has a low input noise of 2.1 nV/ $\sqrt{\text{Hz}}$  @ 50 kHz. The input stage drives a folded cascode that consists of a pair of PNP transistors. The folded cascode and current mirror provide a differential to single-ended conversion of signal current. This current then drives the high impedance node (Pin 5), where the  $C_C$  external capacitor is connected. The output stage preserves

this high impedance with a current gain of 5,000, so that the AD8021 can maintain a high open-loop gain even when driving heavy loads.

Two internal diode clamps across the inputs (Pins 2 and 3) protect the input transistors from large voltages that could otherwise cause emitter-base breakdown, which would result in degradation of offset voltage and input bias current.

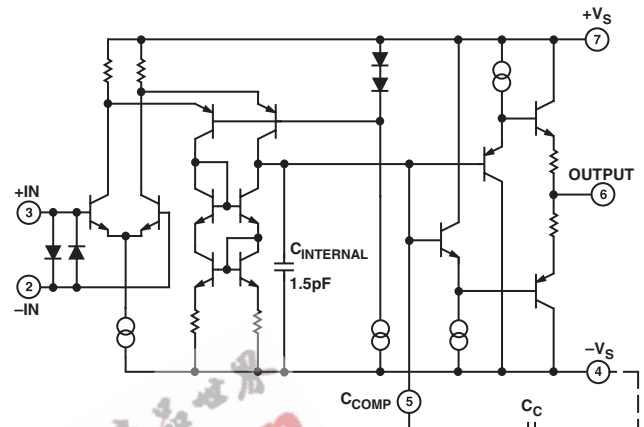

Figure 6. Simplified Schematic

### PCB LAYOUT CONSIDERATIONS

As with all high speed op amps, achieving optimum performance from the AD8021 requires careful attention to PC board layout. Particular care must be exercised to minimize lead lengths between the ground leads of the bypass capacitors and between the compensation capacitor and the negative supply. Otherwise, lead inductance can influence the frequency response and even cause high frequency oscillations. Use of a multilayer printed circuit board, with an internal ground plane, will reduce ground noise and enable a compact component arrangement.

Due to the relatively high impedance of Pin 5 and low values of the compensation capacitor, a guard ring is recommended. The guard ring is simply a PC trace that encircles Pin 5 and is connected to the output, Pin 6, which is at the same potential as Pin 5. This serves two functions. It shields Pin 5 from any local circuit noise generated by surrounding circuitry. It also minimizes stray capacitance, which would tend to otherwise reduce the bandwidth. An example of a guard ring layout may be seen in Figure 7.

Also shown in Figure 7, the compensation capacitor is located immediately adjacent to the edge of the AD8021 package, spanning Pin 4 and Pin 5. This capacitor must be a high quality surface-mount COG or NPO ceramic. The use of leaded capacitors is not recommended. The high frequency bypass capacitor(s) should be located immediately adjacent to the supplies, Pins 4 and 7.

To achieve the shortest possible lead length at the inverting input, the feedback resistor  $R_F$  is located beneath the board and just spans the distance from the output, Pin 6, to inverting input Pin 2. The return node of resistor  $R_G$  should be situated as closely as possible to the return node of the negative supply bypass capacitor connected to Pin 4.

Figure 7. Recommended Location of Critical Components and Guard Ring

### DRIVING 16-BIT ADCS

Low noise and adjustable compensation make the AD8021 especially suitable as a buffer/driver for high resolution analog-to-digital converters.

As seen in TPC 15, the harmonic distortion is better than 90 dB at frequencies between 100 kHz and 1 MHz. This is a real advantage for complex waveforms that contain high frequency information, as the phase and gain integrity of the sampled waveform can be preserved throughout the conversion process. The increase in loop gain results in improved output regulation and lower noise when the converter input changes state during a sample. This advantage is particularly apparent when using 16-bit high resolution ADCs with high sampling rates.

Figure 8 shows a typical ADC driver configuration. The AD8021 is in an inverting gain of  $-7.5$ ,  $f_c$  is 65 kHz, and its output voltage is 10 V p-p. The results are listed in Table II.

Figure 8. Inverting ADC Driver, Gain =  $-7.5$ ,  $f_c = 65$  kHz

Table II. Summary of ADC Driver Performance,  $f_c = 65$  kHz,  $V_{OUT} = 10$  V p-p

Parameter	Measurement	Unit
Second Harmonic Distortion	-101.3	dB
Third Harmonic Distortion	-109.5	dB
THD	-100.0	dB
SFDR	100.3	dB

Figure 9. Noninverting ADC Driver, Gain = 10,  $f_c = 100$  kHz

Table III. Summary of ADC Driver Performance,  $f_c = 100$  kHz,  $V_{OUT} = 20$  V p-p

Parameter	Measurement	Unit
Second Harmonic Distortion	-92.6	dB
Third Harmonic Distortion	-86.4	dB
THD	-84.4	dB
SFDR	5.4	dB

Figure 9 shows another ADC driver connection. The circuit was tested with a noninverting gain of 10.1 and an output voltage of approximately 20 V p-p for optimum resolution and noise performance. No filtering was used. An FFT was performed using Analog Devices' evaluation software for the AD7665 16-bit converter. The results are listed in Table III.

### DIFFERENTIAL DRIVER

The AD8021 is uniquely suited as a low noise differential driver for many ADCs, balanced lines, and other applications requiring differential drive. If pairs of internally compensated op amps are configured as inverter and follower, the noise gain of the inverter will be higher than that of the follower section, resulting in an imbalance in the frequency response (see Figure 11).

A better solution takes advantage of the external compensation feature of the AD8021. By reducing the  $C_{COMP}$  value of the inverter, its bandwidth may be increased to match that of the follower, avoiding compromises in gain bandwidth and phase delay. The inverting and noninverting bandwidths can be closely matched using the compensation feature, thus minimizing distortion.

# AD8021

Figure 10 illustrates an inverter-follower driver circuit operating at a gain of 2, using individually compensated AD8021s. The values of feedback and load resistors were selected to provide a total load of less than 1 kΩ, and the equivalent resistances seen at each op amp's inputs were matched to minimize offset voltage and drift. Figure 12 is a plot of the resulting ac responses of driver halves.

Figure 12. AC Response of Two Dissimilarly Compensated AD8021 Op Amps (Figure 11) Configured for Gains of +2 and -2. Note the Close Gain Match.

## USING THE AD8021 IN ACTIVE FILTERS

The low noise and high gain bandwidth of the AD8021 make it an excellent choice in active filter circuits. Most active filter literature provides resistor and capacitor values for various filters but neglects the effect of the op amp's finite bandwidth on filter performance; ideal filter response with infinite loop gain is implied. Unfortunately, real filters do not behave in this manner. Instead, they exhibit finite limits of attenuation, depending on the gain bandwidth of the active device. Good low-pass filter performance requires an op amp with high gain bandwidth for attenuation at high frequencies, and low noise and high dc gain for low frequency, pass-band performance.

Figure 13 shows the schematic of a 2-pole, low-pass active filter, and Table IV lists typical component values for filters having a Bessel-type response with gains of 2 and 5. Figure 14 is a network analyzer plot of this filter's performance.

Figure 13. Schematic of a Second-Order Low-Pass Active Filter

Gain	R1 (Ω)	R2 (Ω)	R <sub>F</sub> (Ω)	R <sub>S</sub> (Ω)	C1	C2	C <sub>C</sub>
2	71.5	215	499	499	10 nF	10 nF	7 pF
5	44.2	365	90.9	365	10 nF	10 nF	2 pF

Figure 14. Frequency Response of the Filter Circuit of Figure 13 for Two Different Gains

**Driving Capacitive Loads**

When the AD8021 drives a capacitive load, the high frequency response may show excessive peaking before it rolls off. Two techniques can be used to improve stability at high frequency and reduce peaking. The first technique is to increase the compensation capacitor,  $C_C$ , which reduces the peaking while maintaining gain flatness at low frequencies. The second technique is to add a resistor,  $R_{SNUB}$ , in series between the output pin of the AD8021 and the capacitive load,  $C_L$ . Figure 15 shows the response of the AD8021 when both  $C_C$  and  $R_{SNUB}$  are used to reduce peaking. For a given  $C_L$ , Figure 16 can be used to determine the value of  $R_{SNUB}$  that maintains 2 dB of peaking in the frequency response. Note, however, that using  $R_{SNUB}$  attenuates the low frequency output by a factor of  $R_{LOAD}/(R_{SNUB} + R_{LOAD})$ .
