

**VOLTAGE DETECTOR****AZ70XX****General Description**

The AZ70XX series ICs are under voltage detectors with a built in voltage threshold and low power consumption. The AZ70XX are specifically designed to accurately monitor power supplies.

The AZ70XX use a precision on-chip voltage reference and a comparator to measure the input operating voltage. These ICs can accurately reset the system after detecting voltage at the time of switching power on and instantaneous power off in various CPU systems and other logic systems. The detect voltage thresholds are 2.3V/2.5V/2.7V/2.9V/3.1V/3.3V/4.2V/4.5V for AZ7023/25/27/29/31/33/42/45 respectively. Built in hysteresis helps to prevent erratic operation in the presence of noise.

The AZ70XX series are available in 2 standard packages: TO-92 and SOT-89-3.

Features

- Low Current Consumption:
 $I_{CCL}=300\mu\text{A}$ Typical
 $I_{CCH}=30\mu\text{A}$ Typical
- Low Minimum Operating Voltage for Output Resetting: 0.8V Typical
- Built in Hysteresis Voltage: 50mV Typical
- Open Collector Output
- Extended Temperature Range: -40 to 85°C

Applications

- Low Battery Voltage Detector
- Power Fail Indicator
- Processor Reset Generator
- Battery Backup Control
- Home Electric Appliances

Operating Diagram

Figure 12. AZ70XX Timing Waveform

**VOLTAGE DETECTOR****AZ70XX****Operating Diagram (Continued)**

Figure 12 is a typical timing waveform for AZ70XX during power-up and temporary power-down period. Here is some explanations for AZ70XX's operation.

1. During power-up period, V_{OUT} will remain undefined until V_{CC} rises above V_{OPR} (typically 0.8V). After that moment, the output will become valid and will be at its logic low state while $V_{OPR} < V_{CC} < V_S$ for power-up operating.

2. After a delay time of t_{pLH} from the moment $V_{CC} > V_S$, the V_{OUT} will be at its logic high state. In general, V_{OUT} is dependent upon the voltage that the pull up resistor connected to.

3. During power-down, after a delay time of t_{pHL} from the moment $V_{CC} < V_S - V_{HYS}$, V_{OUT} will be at its logic low state. In general, at rated output current and V_{CC} , V_{OUT} can be pulled down to a voltage as low as within 0.4V from GND. (See the Electrical Characteristics section).

4. V_{OUT} will be at its logic low state while $V_S - V_{HYS} > V_{CC} > V_{OPR}$ for power-down operating.

5. After V_{CC} falls below V_{OPR} , the output is undefined.
