

10-Bit, 275MSPS Analog-to-Digital Converter

Description

The Kenet **KAD2710L** is the industry's lowest power, 10-bit, high performance Analog-to-Digital converter. The converter runs at sampling rates up to 275MSPS, and is fabricated with Kenet's proprietary *FemtoCharge*® CMOS technology. Users can now obtain industry-leading SNR and SFDR specifications while nearly halving power consumption. Sampling rates of 210, 170 and 105MSPS are also available in the same pin-compatible package and in versions with 8-bit resolution. Kenet's KAD2710C offers this performance with LVCMOS outputs. All are available in 68-pin RoHS-compliant QFN packages with exposed paddle. Performance is specified over the full industrial temperature range (-40 to +85°C).

Key Specifications

- SNR of 56dB at Nyquist
- SFDR of 71dBc at Nyquist
- Power consumption $\leq 280\text{mW}$ at $f_s = 275\text{MSPS}$

Features

- On-chip reference
- Internal track and hold
- 1.5V_{PP} differential input voltage
- 600MHz analog input bandwidth
- Two's complement or binary output
- Over-range indicator
- Selectable $\div 2$ Clock Input
- LVDS compatible outputs

Applications

- High-Performance Data Acquisition
- Portable Oscilloscope
- Medical Imaging
- Cable Head Ends
- Power-Amplifier Linearization
- Radar and Satellite Antenna Array Processing
- Broadband Communications
- Local Multipoint Distribution System (LMDS)
- Communications Test Equipment

Resolution, Speed	LVDS Outputs	LVCMOS Outputs

Junction Temperature		150	°C

1. Exposing the device to levels in excess of the maximum ratings may cause permanent damage. Exposure to maximum conditions for extended periods may affect device reliability.

Thermal Impedance

Parameter	Symbol	Typ	Unit
Junction to Paddle ²	Φ_{JP}	30	°C/W

2. Paddle soldered to ground plane.

ESD

Electrostatic charge accumulates on humans, tools and equipment, and may discharge through any metallic package contacts (pins, balls, exposed paddle, etc.) of an integrated circuit. Industry-standard protection techniques have been utilized in the design of this product. However, reasonable care must be taken in the storage and handling of ESD sensitive products. Contact Kenet for the specific ESD sensitivity rating of this product.

KAD2710L 10-Bit, 275MSPS Analog-to-Digital Converter

Electrical Specifications

All specifications apply under the following conditions unless otherwise noted: AVDD2 = 1.8V, AVDD3 = 3.3V, OVDD = 1.8V. T_A = -40°C to +85°C, Typ values at 25°C. f_{SAMPLE} = 275MSPS, f_{IN} = Nyquist.

DC Specifications

Parameter	Symbol	Conditions	Min	Typ	Max	Units
Power Requirements						
1.8V Analog Supply Voltage	AVDD2		1.7	1.8	1.9	V

KAD2710L 10-Bit, 275MSPS Analog-to-Digital Converter

Functional Description

The KAD2710 is based upon a ten bit, 275MSPS A/D converter in a pipelined architecture. The input voltage is captured by a sample & hold circuit and converted to a unit of charge. Proprietary charge domain techniques are used to compare the input to a series of reference charges. These comparisons determine the digital code for each input value. The converter pipeline requires 24 sample clocks to produce a result. Digital error correction is also applied, resulting in a total latency of 28 clock cycles. This is evident to the user as a latency between the start of a conversion and the data being available on the digital outputs.

At start-up, a self-calibration is performed to minimize gain and offset errors. The reset pin (RST) is initially held low internally at power-up and will remain in that state until the calibration is complete. The clock frequency should remain fixed during this time.

Calibration accuracy is maintained for the sample rate at which it is performed, and therefore should be repeated if the clock frequency is changed by more than 10%. Recalibration can be initiated via the RST pin, or power cycling, at any time.

Reset

The KAD2710L resets and calibrates automatically on power-up. To force a reset and initiate recalibration of the ADC after power-up, connect an open-drain output device to drive pin 28 (RST) and pull low for at least ten sample clock periods. Do not use a device with a pull-up on the reset pin, as it may prevent the KAD2710 from properly executing the power-on reset.

Voltage Reference

The VREF pin is the full-scale reference, which sets the full-scale input voltage for the chip and requires a bypass capacitor of 0.1 μ F or larger. An internally generated reference voltage is provided from a bandgap voltage buffer. This buffer can sink or source up to 50 μ A externally.

An external voltage may be applied to this pin to provide a more accurate reference than the internally generated bandgap voltage or to match the full-scale reference among a system of KAD2710L chips. One option in the latter configuration is to use one KAD2710L's internally generated reference as the

external reference voltage for the other chips in the system. Additionally, an externally provided reference can be changed from the nominal value to adjust the full-scale input voltage within a limited range.

To select whether the full-scale reference is internally generated or externally provided, the digital input port VREFSEL should be set appropriately, low for internal or high for external. This pin also has an internal 18k Ω pull-up resistor. To use the internally generated reference VREFSEL can be tied directly to AVSS, and to use an external reference VREFSEL can be allowed to float.

Analog Input

The fully differential ADC input (INP/INN) connects to the sample and hold circuit. The ideal full-scale input voltage is 1.5V_{PP}, centered at the VCM voltage of 0.86V as shown in Figure 18.

Figure 18. Analog Input Range

Best performance is obtained when the analog inputs are driven differentially in an ac-coupled configuration. The common mode output voltage, VCM, should be used to properly bias each input as shown in Figures 19 and 20. An RF transformer will give the best noise and distortion performance for wideband and/or high intermediate frequency (IF) inputs. The recommended biasing is shown in Figure 19.

Figure 19. Transformer Input

KAD2710L 10-Bit, 275MSPS Analog-to-Digital Converter

The value of the shunt resistor should be determined based on the desired termination impedance. The differential input impedance of the KAD2710 is 10MΩ.

A differential amplifier can be used in applications that require dc coupling, at the expense of reduced dynamic performance. In this configuration the amplifier will typically reduce the achievable SNR and distortion performance. A typical differential amplifier configuration is shown in Figure 20.

Figure 20. Differential Amplifier Input

Clock Input

The clock input circuit is a differential pair (see Figure 24). Driving these inputs with a high level (up to 1.8V_{PP} on each input) sine or square wave will provide the lowest jitter performance. The recommended drive circuit is shown in Figure 21. The clock inputs can be driven single-ended, but this is not recommended as performance will suffer.

Figure 21. Recommended Clock drive

The CLKDIV pin is a 1.8V CMOS control pin (input) that selects whether the input clock frequency is passed directly to the ADC or divided by two. Applying a low level will divide by two; 1.8V applied (or left floating) will not divide.

Use of the clock divider is optional. The KAD2710L's ADC requires a clock with 50% duty cycle for optimum performance. If such a clock is not available, one option is to generate twice the desired sampling

rate, then use the KAD2710L's divide-by-2 to generate a 50%-duty-cycle clock. The divider only uses the rising edge of the clock, so 50% clock duty cycle is assured.

CLKDIV Pin	Divide Ratio
AVSS	2
AVDD	1

Table 3. CLKDIV Pin Settings

Jitter

In a sampled data system, clock jitter directly impacts the achievable SNR performance. The theoretical relationship between clock jitter and maximum SNR is shown in Equation 1 and is illustrated in Figure 22.

$$SNR = 20 \log_{10} \left(\frac{1}{2\pi f_{IN} t_J} \right)$$

Where t_J is the RMS uncertainty in the sampling instant.

Equation 1.

This relationship shows the SNR that would be achieved if clock jitter were the only non-ideal factor. In reality, achievable SNR is limited by internal factors such as dc linearity (DNL), aperture jitter and thermal noise.

Figure 22. SNR vs. Clock Jitter

Any internal aperture jitter combines with the input clock jitter, in a root-sum-square fashion since they are not statistically correlated, and this determines the total jitter in the system. The total jitter, combined with other noise sources, then determines the achievable SNR.

Equivalent Circuits

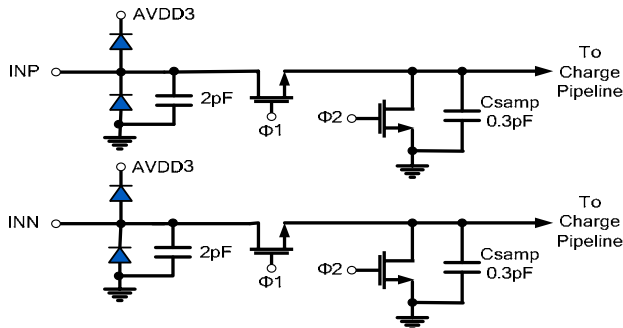

Figure 23. Analog Inputs

Figure 24. Clock Inputs

Figure 25. LVDS Outputs

Layout Considerations

Split Ground and Power Planes

Data converters operating at high sampling frequencies require extra care in PC board layout. Many complex board designs benefit from isolating the analog and digital sections. Analog supply and ground planes should be laid out under signal and clock inputs. Locate the digital planes under outputs and logic pins. Grounds should be joined under the chip.

Clock Input Considerations

Use matched transmission lines to the inputs for the analog input and clock signals. Locate transformers, drivers and terminations as close to the chip as possible.

Bypass and Filtering

Bulk capacitors should have low equivalent series resistance. Tantalum is a good choice. For best performance, keep ceramic bypass capacitors very close to device pins. Longer traces will increase inductance, resulting in diminished dynamic performance and accuracy. Make sure that connections to ground are direct and low impedance. Avoid forming ground loops.

LVDS Outputs

Output traces and connections must be designed for 50Ω (100Ω differential) characteristic impedance. Keep traces direct, and minimize bends where possible. Avoid crossing ground and power plane breaks with signal traces.

Unused Inputs

Three of the four standard logic inputs (RESET, CLKDIV, 2SC) which will not be operated do not require connection for best ADC performance. These inputs can be left open if they are not used. VREFSEL must be held low for internal reference, but can be left open for external reference.

KAD2710L 10-Bit, 275MSPS Analog-to-Digital Converter

Definitions

Analog Input Bandwidth is the analog input frequency at which the spectral output power at the fundamental frequency (as determined by FFT analysis) is reduced by 3dB from its full-scale low-frequency value. This is also referred to as Full Power Bandwidth.

Aperture Delay or Sampling Delay is the time required after the rise of the clock input for the sampling switch to open, at which time the signal is held for conversion.

Aperture Jitter is the RMS variation in aperture delay for a set of samples.

Clock Duty Cycle is the ratio of the time the clock wave is at logic high to the total time of one clock period.

Differential Non-Linearity (DNL) is the deviation of any code width from an ideal 1 LSB step.

Effective Number of Bits (ENOB) is an alternate method of specifying Signal to Noise-and-Distortion Ratio (SINAD). In dB, it is calculated as: $ENOB = (SINAD - 1.76) / 6.02$.

Integral Non-Linearity (INL) is the deviation of each individual code from a line drawn from negative full-scale (1/2 LSB below the first code transition) through positive full-scale (1/2 LSB above the last code transition). The deviation of any given code from this line is measured from the center of that code.

Least Significant Bit (LSB) is the bit that has the smallest value or weight in a digital word. Its value in terms of input voltage is $VFS / (2^N - 1)$ where N is the resolution in bits.

Missing Codes are output codes that are skipped and will never appear at the ADC output. These codes cannot be reached with any input value.

Most Significant Bit (MSB) is the bit that has the largest value or weight. Its value in terms of input voltage is $VFS / 2$.

Pipeline Delay is the number of clock cycles between the initiation of a conversion and the appearance at the output pins of the corresponding data.

Power Supply Rejection Ratio (PSRR) is the ratio of a change in power supply voltage to the input voltage necessary to negate the resultant change in output code.

Signal to Noise-and-Distortion (SINAD) is the ratio of the RMS signal amplitude to the RMS value of the sum

of all other spectral components below one half the clock frequency, including harmonics but excluding DC.

Signal-to-Noise Ratio (without Harmonics) is the ratio of the RMS signal amplitude to the sum of all other spectral components below one-half the sampling frequency, excluding harmonics and DC.

Spurious-Free-Dynamic Range (SFDR) is the ratio of the RMS signal amplitude to the RMS value of the peak spurious spectral component. The peak spurious spectral component may or may not be a harmonic.

Two-Tone SFDR is the ratio of the RMS value of either input tone to the RMS value of the peak spurious component. The peak spurious component may or may not be an IMD product.
