

### FEATURES

**Significant Performance Advantages over LF155 and LF157 Devices**

**Low Input Offset Voltages: 500  $\mu\text{V}$  Max**  
**Low Input Offset Voltage Drift: 2.0  $\mu\text{V}/^\circ\text{C}$**   
**Minimum Slew Rate Guaranteed on All Models**  
**Temperature-Compensated Input Bias Currents**  
**Bias Current Specified Warmed-Up Over Temperature**  
**Internal Compensation**  
**Low Input Noise Current: 0.01  $\text{pA}/\sqrt{\text{Hz}}$**   
**High Common-Mode Rejection Ratio: 100 dB**  
**Models with MIL-STD 883 Processing Available**

### OP15

**156 Speed with 155 Dissipation: 80 mW Typ**  
**Wide Bandwidth: 6 MHz**  
**High Slew Rate: 13  $\text{V}/\mu\text{s}$**   
**Fast Settling to  $\pm 0.1\%$ : 1,200 ns**

### OP17

**Highest Slew Rate: 60  $\text{V}/\mu\text{s}$**   
**Fastest Settling to  $\pm 0.1\%$ : 600 ns**  
**Highest Gain Bandwidth Product ( $A_{\text{VCL}} = 5 \text{ Min}$ ): 30 MHz**  
**Guaranteed Input Bias Current @ 125 $^\circ\text{C}$**

### GENERAL DESCRIPTION

The ADI-JFET input series of devices offer clear advantages over industry-generic devices and are superior in both cost and performance to many dielectrically-isolated and hybrid op amps. All devices offer offset voltages as low as 0.5 mV with  $\text{TCV}_{\text{OS}}$  guaranteed to 5  $\mu\text{V}/^\circ\text{C}$ . A unique input bias cancellation circuit reduces the  $I_{\text{B}}$  by a factor 10 over conventional designs. In addition ADI specifies  $I_{\text{B}}$  and  $I_{\text{OS}}$  with the devices warmed up and operating at 25 $^\circ\text{C}$  ambient.

These devices were designed to provide real precision performance along with high speed. Although they can be nulled, the design objective was to provide low offset-voltage without nulling. Systems generally become more cost effective as the number of trim circuits is decreased. ADI achieves this performance by use of an improved bipolar compatible JFET process coupled with on chip, zener-zap offset trimming.

The OP15 provides an excellent combinations of high speed and low input offset voltage. In addition, the OP15 offers the speed of the 156A op amp with the power dissipation of a 155A. The combination of a low input offset voltage of 500  $\mu\text{V}$ , slew rate of 13  $\text{V}/\mu\text{s}$ , and settling time of 1,200 ns to 0.1% makes the OP15 an op amp of both precision and speed. The additional features of low supply current coupled with an input bias current makes the OP15 ideal for a wide range of applications.

The OP17 has a slew rate of 60  $\text{V}/\mu\text{s}$  and is the best choice for applications requiring high closed-loop gain with high speed. See OP42 datasheet for unity gain applications and the OP215 datasheet for a dual configuration of the OP15.

### NOTES

<sup>1</sup>Input bias current is specified for two different conditions. The  $T_J = 25^\circ\text{C}$  specification is with the junction at ambient temperature; the device operating specification is with the device operating in a warmed-up condition at  $25^\circ\text{C}$  ambient. The warmed-up bias current value is correlated to the junction temperature value via the curves of  $I_B$  versus  $T_J$  and  $I_B$  versus  $T_A$ . ADI has a bias current compensation circuit which gives improved bias current over the standard JFET input op amps.  $I_B$  and  $I_{OS}$  are measured at  $V_{CM} = 0$ .

<sup>2</sup>Settling time is defined here for a unity gain inverter connection using  $2\ \text{k}\Omega$  resistors. It is the time required for the error voltage (the voltages at the inverting input pin on the amplifier) to settle to within a specified percent of its final value from the time a  $10\ \text{V}$  step input is applied to the inverter. See settling time test circuit.

<sup>3</sup>Sample tested.

<sup>4</sup>Settling time is defined here for  $A_V = -5$  connection with  $R_F = 2\ \text{k}\Omega$ . It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within  $0.01\%$  of its final value from the time a  $2\ \text{V}$  step input is applied to the inverter. See settling time test circuit.

APPLICATION INFORMATION

Dynamic Operating Considerations

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance for the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to ac ground set the frequency of this pole. In many instances the frequency of this pole is much greater than the expected, 3 dB frequency of the close-loop gain, and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency, a lead capacitor should be placed from the output to the negative input of the op amp. The value of the added capacitor should be such that the RC time-constant of this capacitor and the resistance it parallels is greater than, or equal to, the original feedback pole time constant.
