## WINBOND H/W MONITORING IC

### 1. GENERAL DESCRIPTION

W83782D is an evolving version of W83782D --- Winbond's most popular hardware status monitoring IC. The W83782D can be used to monitor several critical hardware parameters of the system, including power supply voltages, fan speeds, and temperatures, which are very important for a high-end computer system to work stable and properly. W83782D provides both ISA and I<sup>2</sup>C<sup>TM</sup> serial bus interface.

An 8-bit analog-to-digital converter (ADC) was built inside W83782D. The W83782D can simultaneously monitor 9 analog voltage inputs, 2 fan tachometer inputs, 3 remote temperature, one case-open detection signal. The remote temperature sensing can be performed by thermistors, or 2N3904 NPN-type transistors, or directly from Intel<sup>TM</sup> Deschutes CPU thermal diode output. Also the W83782D provides: 4 PWM (pulse width modulation) outputs for the fan speed control; beep tone output for warning; SMI#, OVT#, GPO# signals for system protection events.

Through the application software or BIOS, the users can read all the monitored parameters of system from time to time. And a pop-up warning can be also activated when the monitored item was out of the proper/preset range. The application software could be Winbond's Hardware Doctor<sup>TM</sup>, or Intel<sup>TM</sup> LDCM (LanDesk Client Management), or other management application software. Also the users can set up the upper and lower limits (alarm thresholds) of these monitored parameters and to activate one programmable and maskable interrupts. An optional beep tone could be used as warning signal when the monitored parameters is out of the preset range.

Additionally, 5 VID inputs are provided to read the VID of CPU (i.e. Pentium<sup>TM</sup> II) if applicable. This is to provide the Vcore voltage correction automatically. Also W83782D uniquely provides an optional feature: early stage (before BIOS was loaded) beep warning. This is to detect if the fatal elements present --- Vcore or +3.3V voltage fail, and the system can not be boomed up. Also there are 3 specific pins to provide selectable address setting for application of multiple devices (up to 8 devices) wired through I<sup>2</sup>C<sup>TM</sup> interface.

## 6. FUNCTIONAL DESCRIPTION

### 6.1 General Description

The W83782D provides 7 analog positive inputs, 3 fan speed monitors, at most 4 sets for fan PWM (Pulse Width Modulation) control, 3 thermal inputs from remote thermistors or 2N3904 transistors or Pentium™ II (Deschutes) thermal diode outputs, case open detection and beep function output when the monitor value exceed the set limit value including voltage, temperature, or fan counter. When start the monitor function on the chip, the watch dog machine monitor every function and store the value to registers. If the monitor value exceeds the limit value, the interrupt status will be set to 1.

### 6.2 Access Interface

The W83782D provides two interface for microprocessor to read/write internal registers.

#### 6.2.1 ISA interface

The first interface uses ISA Bus to access which the ports of low byte (bit2~bit0) are defined in the port 5h and 6h. The high byte (from ISA address bus bit15~bit3) of these ports is decoded by Chip Select (CS#), the general decoded address is set to port 295h and port 296h. These two ports are described as following:

Port 295h: W83782D Index register port.

Port 296h: Data port.

The register structure is showed as the Figure 1.

# Preliminary W83782D

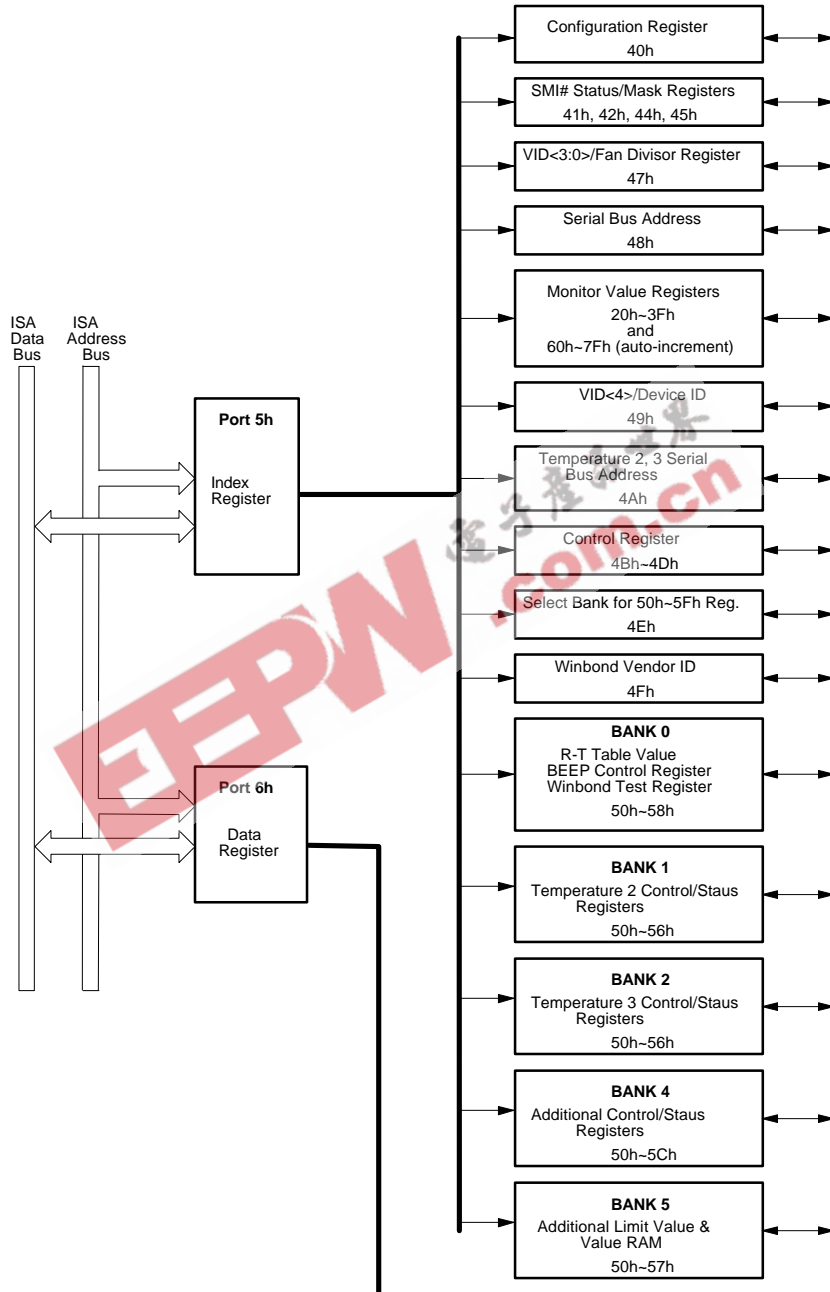

Figure 1. ISA interface access diagram

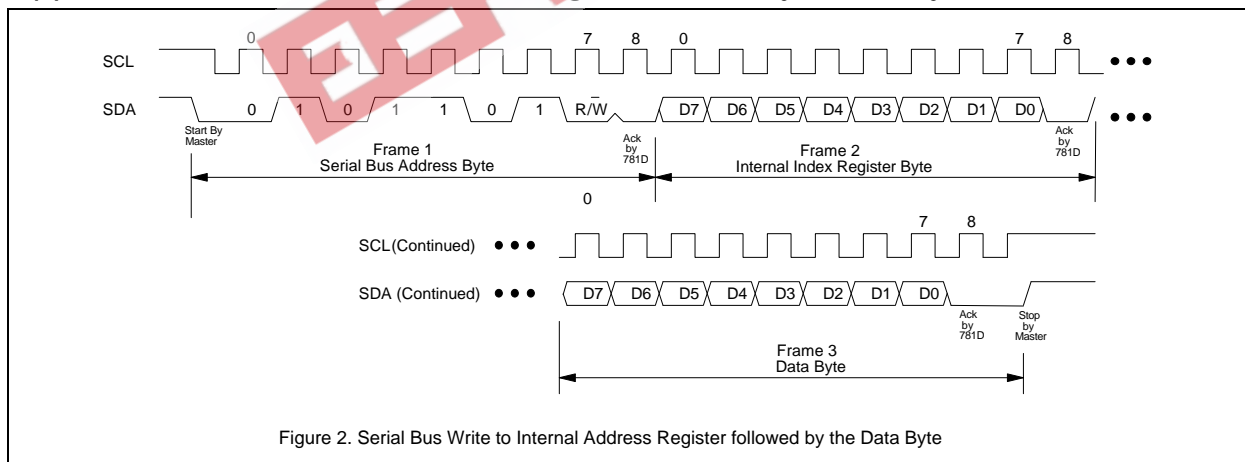

## 6.2.2 I<sup>2</sup>C interface

The second interface uses I<sup>2</sup>C Serial Bus. In the W83782D has three serial bus address. That is, the first address defined at CR[48h] can read/write all registers excluding Bank 1 and Bank 2 temperature sensor 2/3 registers. The second address defined at CR[4Ah] bit2-0 only read/write temperature sensor 2 registers, and the third address defined at CR[4Ah] bit6-4 only can access (read/write) temperature sensor 3 registers.

The first serial bus address of W83782D has 3 hardware setting bits set by pin47-45 when pin 43 is set to high. The address is 00101[pin45][pin46][pin47]. If pin45=1, pin46=1, pin47=0, for example, the content of CR[48h] is 00101110. If CR[4Ah] bit 2-0 is XXX, the temperature sensor 2 serial address is 1001XXXG, in which G is the read/write bit. If CR[4Ah] bit 6-4 is YYY, the temperature sensor 3 serial address is 1001YYYG, in which G is the read/write bit.

## 6.2.3 The first serial bus access timing are shown as follow:

## 6.3 Analog Inputs

The maximum input voltage of the analog pin is 4.096V because the 8-bit ADC has a 16mV LSB. Really, the application of the PC monitoring would most often be connected to power suppliers. The CPU V-core voltage ,+3.3V and battery voltage can directly connected to these analog inputs. The 5VSB and +12V inputs should be reduced a factor with external resistors so as to obtain the input range. As Figure 11 shows.

Figure 11.

### 6.3.1 Monitor over 4.096V voltage:

The input voltage +12VIN can be expressed as following equation.

$$12VIN = V_1 \times \frac{R_2}{R_1 + R_2}$$

The value of R1 and R2 can be selected to 28K Ohms and 10K Ohms, respectively, when the input voltage V1 is 12V. The node voltage of +12VIN can be subject to less than 4.096V for the maximum input range of the 8-bit ADC. Similarly, the node voltage of 5VSB (measure standby power VSB for ATX power supply) also can be evaluated by using two series resistors R3 and R4 which real value can be 5.1K ohms and 7.5K ohms so as to obtain the 5VSB is limited to less than 4.096V. The Pin 33 is connected to the power supply VCC with +5V. There are two functions in this pin with 5V. The first function is to supply internal analog power in the W83782D and the second function is that this voltage with 5V is connected to internal serial resistors to monitor the +5V voltage. The value of two serial resistors are 34K ohms and 50K ohms so that input voltage to ADC is 2.98V which is less than 4.096V of ADC maximum input voltage. The express equation can represent as follows.

$$V_{in} = VCC \times \frac{50K\Omega}{50K\Omega + 34K\Omega} \cong 2.98V$$

where VCC is set to 5V.

### 6.3.2 Monitor negative voltage:

The negative voltage should be connected two series resistors and a positive voltage VREF (is equal to 3.6V). In the Figure 11, the voltage V3 and V4 are two negative voltage which they are -12V and -5V respectively. The voltage V3 is connected to two serial resistors then is connected to another terminal VREF which is positive voltage. So as that the voltage node N12VIN can be obtain a posedge voltage if the scales of the two serial resistors are carefully selected. It is recommended from Winbond that the scale of two serial resistors are R5=232K ohms and R6=56K ohm. The input voltage of node -12VIN can be calculated by following equation.

$$N12VIN = (VREF + |V_5|) \times \left( \frac{232K\Omega}{232K\Omega + 56K\Omega} \right) + V_5$$

where VREF is equal 3.6V.

If the V<sub>5</sub> is equal to -12V then the voltage is equal to 0.567V and the converted hexadecimal data is set to 35h by the 8-bit ADC with 16mV-LSB. This monitored value should be converted to the real negative voltage and the express equation is shown as follows.

$$V_5 = \frac{N12VIN - VREF \times b}{1 - b}$$

Where  $b$  is  $232K/(232K+56K)$ . If the N2VIN is 0.567 then the V5 is approximately equal to -12V.

The another negative voltage input V6 (approximate -5V) also can be evaluated by the similar method and the serial resistors can be selected with  $R7=120K$  ohms and  $R8=56K$  ohms by the Winbond recommended. The expression equation of V6 With -5V voltage is shown as follows.

$$V_6 = \frac{N5VIN - VREF \times g}{1 - g}$$

Where the  $b$  is set to  $120K/(120K+56K)$ . If the monitored ADC value in the N5VIN channel is 0.8635,  $VREF=3.6V$  and the parameter  $b$  is 0.6818 then the negative voltage of V6 can be evaluated to be -5V.

### 6.3.3 Monitor temperature from thermistor:

The W83782D can connect three thermistors to measure three different environment temperature. The specification of thermistor should be considered to (1)  $\beta$  value is 3435K, (2) resistor value is 10K ohms at 25°C. In the Figure 11, the thermistor is connected by a serial resistor with 10K Ohms, then connect to VREF (Pin 37).

### 6.3.4 Monitor temperature from Pentium II™ thermal diode or bipolar transistor 2N3904

The W83782D can alternate the thermistor to Pentium II™ (Deschutes) thermal diode interface or transistor 2N3904 and the circuit connection is shown as Figure 12. The pin of Pentium II™ D- is connected to power supply ground (GND) and the pin D+ is connected to pin PIITDx in the W83782D. The resistor  $R=30K$  ohms should be connected to VREF to supply the diode bias current and the bypass capacitor  $C=3300pF$  should be added to filter the high frequency noise. The transistor 2N3904 should be connected to a form with a diode, that is, the Base (B) and Collector (C) in the 2N3904 should be tied together to act as a thermal diode.

Figure 12.

## 6.4 FAN Speed Count and FAN Speed Control

### 6.4.1 Fan speed count

Inputs are provided for signals from fans equipped with tachometer outputs. The level of these signals should be set to TTL level, and maximum input voltage can not be over +5.5V. If the input signals from the tachometer outputs are over the VCC, the external trimming circuit should be added to reduce the voltage to obtain the input specification. The normal circuit and trimming circuits are shown as Figure 13.

Determine the fan counter according to:

$$\text{Count} = \frac{1.35 \times 10^6}{\text{RPM} \times \text{Divisor}}$$

In other words, the fan speed counter has been read from register CR28 or CR29 or CR2A, the fan speed can be evaluated by the following equation.

$$\text{RPM} = \frac{1.35 \times 10^6}{\text{Count} \times \text{Divisor}}$$

The default divisor is 2 and defined at CR47.bit7~4, CR4B.bit7~6, and Bank0 CR5D.bit5~7 which are three bits for divisor. That provides very low speed fan counter such as power supply fan. The followed table is an example for the relation of divisor, PRM, and count.

Divisor	Nominal PRM	Time per Revolution	Counts	70% RPM	Time for 70%
1	8800	6.82 ms	153	6160	9.74 ms

## 6.4.2 Fan speed control

The W83782D provides four sets for fan PWM speed control. The duty cycle of PWM can be programmed by a 8-bit registers which are defined in the Bank0 CR5A, CR5B, CR5E, and CR5F. The default duty cycle is set to 100%, that is, the default 8-bit registers is set to FFh. The expression of duty can be represented as follows.

$$\text{Duty - cycle(\%)} = \frac{\text{Programmed 8 - bit Register Value}}{255} \times 100\%$$

The PWM clock frequency also can be program and defined in the Bank0.CR5C and Bank4.CR5C. The application circuit is shown as follows.

Figure 14.

## 6.5 Temperature Measurement Machine

The temperature data format is 8-bit two's complement for sensor 1 and 9-bit two's complement for sensor 2/3. The 8-bit temperature data can be obtained by reading the CR[27h]. The 9-bit temperature data can be obtained by reading the 8 MSBs from the Bank1/2 CR[50h] and the LSB from the Bank1/2 CR[51h] bit 7. The format of the temperature data is show in Table 1.

## 6.5.1 The W83782D temperature sensor 1 SMI# interrupt has two modes:

### (1) Comparator Interrupt Mode

Setting the  $T_{HYST}$  (Temperature Hysteresis) limit to  $127^{\circ}\text{C}$  will set temperature sensor 1 SMI# to the Comparator Interrupt Mode. Temperature exceeds  $T_O$  (Over Temperature) Limit causes an interrupt and this interrupt will be reset by reading all the Interrupt Status Register. Once an interrupt event has occurred by exceeding  $T_O$ , then reset, if the temperature remains above the  $T_O$ , the interrupt will occur again when the next conversion has completed. If an interrupt event has occurred by exceeding  $T_O$  and not reset, the interrupts will not occur again. The interrupts will continue to occur in this manner until the temperature goes below  $T_O$ . (Figure 16-1 )

### (2) Two-Times Interrupt Mode

Setting the  $T_{HYST}$  lower than  $T_O$  will set temperature sensor 1 SMI# to the Two-Times Interrupt Mode. Temperature exceeding  $T_O$  causes an interrupt and then temperature going below  $T_{HYST}$  will also cause an interrupt if the previous interrupt has been reset by reading all the interrupt Status Register. Once an interrupt event has occurred by exceeding  $T_O$ , then reset, if the temperature remains above the  $T_{HYST}$ , the interrupt will not occur. (Figure 15-2 )

Figure 15-2. Two-Times Interrupt Mode

## 6.5.2 The W83782D temperature sensor 2 and sensor 3 SMI# interrupt has two modes and it is programmed at CR[4Ch] bit 6.

### (1) Comparator Interrupt Mode

Temperature exceeding  $T_O$  causes an interrupt and this interrupt will be reset by reading all the Interrupt Status Register. Once an interrupt event has occurred by exceeding  $T_O$ , then reset, if the temperature remains above the  $T_{HYST}$ , the interrupt will occur again when the next conversion has completed. If an interrupt event has occurred by exceeding  $T_O$  and not reset, the interrupts will not occur again. The interrupts will continue to occur in this manner until the temperature goes below  $T_{HYST}$ . (Figure 16-1)

### (2) Two-Times Interrupt Mode

Temperature exceeding  $T_O$  causes an interrupt and then temperature going below  $T_{HYST}$  will also cause an interrupt if the previous interrupt has been reset by reading all the interrupt Status Register. Once an interrupt event has occurred by exceeding  $T_O$ , then reset, if the temperature remains above the  $T_{HYST}$ , the interrupt will not occur. (Figure 16-2)

Figure 16-1. Comparator Interrupt Mode

Figure 16-2. Two-Times Interrupt Mode

\*Interrupt Reset when Interrupt Status Registers are read

6.5.3 The W83782D temperature sensor 2 and 3 Over-Temperature (OVT#) has two modes, and they are programmed at Bank1 and Bank2 CR[52h] bit1 . These two bits needs to be programmed the same value.

**(1) Comparator Mode :**

Temperature exceeding  $T_O$  causes the OVT# output activated until the temperature is less than  $T_{HYST}$ . ( Figure 17)

**(2) Interrupt Mode:**

Temperature exceeding  $T_O$  causes the OVT# output activated indefinitely until reset by reading temperature sensor 2 or sensor 3 registers. Temperature exceeding  $T_O$  , then OVT# reset, and then temperature going below  $T_{HYST}$  will also cause the OVT# activated indefinitely until reset by reading temperature sensor2 or sensor 3 registers. Once the OVT# is activated by exceeding  $T_O$  , then reset, if the temperature remains above  $T_{HYST}$  , the OVT# will not be activated again.( Figure 17)
